

VI. Tensor Networks in two and higher

discussions

1) Projected Entangled Pair States (PEPS)

PEPS :- good approx. for ground states in 1D

- basis for powerful numerical methods
- framework for analytical modelling

Can we generalize this to 2D (and higher)?

What is the same?

What is different?

Basic intuition behind PEPS:

Area law \Rightarrow entanglement distributed locally

Idea: Build 2D ansatz based on

locality of entanglement.

a) Dependent

Considers 2D lattice

(here: square lattice: easiest to draw)

$$|\psi\rangle = \sum_{i_1, \dots, i_N} c_{i_1, \dots, i_N} |i_1, \dots, i_N\rangle$$

Express c_{i_1, \dots, i_N} as 2D tensor network

with tensor

As in 1D, we can either do this with PBC, terminate the boundaries, or choose site-dep. tensors $A^{[ij]}$.

We can also express such states in the "AKLT way", i.e. with ent. states $|\omega\rangle$

and maps $P: \mathbb{C}^D \otimes \mathbb{C}^D \otimes \mathbb{C}^D \otimes \mathbb{C}^D \rightarrow \mathbb{C}^t$,

$$\text{(e.g., } |\omega\rangle = \sum_{i=1}^D |i\rangle|i\rangle; \quad P = \sum_{\alpha,\beta,\gamma,\delta} A_{\alpha\beta\gamma\delta}^i |i\rangle\langle\alpha,\beta,\gamma,\delta|)$$

Because of this, these states are also called
 "Projected Entangled Pair States" (PEPS)
 - even though I need not be a projection -
 or simply "Tensor Network States" (TNS).

Note: The same construction can be used
 on other lattices, higher dimensions,
 or any graph.

b) Approximability by PEPS

In 1D, area law \Rightarrow ent. distr. locally
 \Rightarrow good MPS approx.

In 2D, "area law \Rightarrow ent. local" does
 not automatically hold.

Do PEPS still provide a good approx. of
 ground states of 2D local Hamiltonians?

Yes! - Using more direct techniques

(Mott's or Taylor expansion, which is truncated) we can get similar result:

Ground states are well approximated to error ϵ with a bond dimension

$$D \sim \left(\frac{N}{\epsilon}\right)^{\log N}$$

i.e., almost polynomial.

(Terms & conditions apply, see arXiv:1406.2973)

\Rightarrow PEPS form a good class of states
to approximate ground states.

2. Examples

a) The GHZ state

$$|4\rangle = |0\dots 0\rangle + |1\dots 1\rangle$$

$$A_{\alpha\beta\gamma\delta}^i = \begin{cases} 1 & : i = \alpha = \beta = \gamma = \delta \\ 0 & : \text{otherwise} \end{cases}$$

b) AKLT state:

$$|0\rangle = \frac{1}{\sqrt{2}}(|01\rangle - |10\rangle)$$

$su(2)$ doublet (spin $1/2$)

$$\frac{1}{2} \otimes \frac{1}{2} \otimes \frac{1}{2} = \frac{1}{2} : \text{spin } 0, 1, 2$$

$$P = \Pi_{S=2}$$

proj. onto perm.-sym. space!

$\rightarrow su(2)$ -invariant spin-2 state.

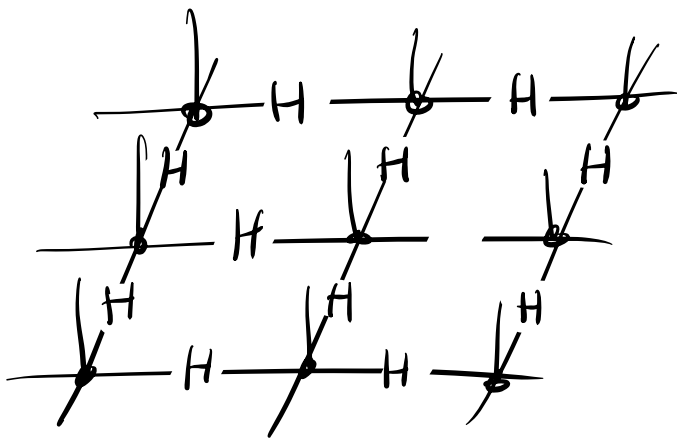

Alternatively: honeycomb lattice.

$$\frac{1}{2} \otimes \frac{1}{2} \otimes \frac{1}{2} = \frac{1}{2} \text{ or } \frac{3}{2} \implies \underbrace{P = \sqrt{11}_{3/2}}_{\text{perm.-sym. space!}}$$

c) 2D cluster state

The 2D cluster state - obtained by acting with $CZ = \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & -1 \end{pmatrix}$ on $|+\rangle^{\otimes N}$ on all edges of the lattice is a PEPS with

$$\alpha_i \delta_j = \delta_{ij} \delta$$

$$-H- = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

(Can be brought into conv. form
e.g. by blocking)

(\rightarrow Homework)

f) PEPS from classical models

Let $H(s_1, \dots, s_N)$ be a classical
statistical model, e.g. the 2D

Ising model

$$H = - \sum_{\langle ij \rangle} s_i s_j, \quad s_i = \pm 1$$

Define

$$|\psi(\beta)\rangle = \sum_{s_1, \dots, s_N} e^{-\beta/2 H(s_1, \dots, s_N)} |s_1, \dots, s_N\rangle$$

This state is a PEPS:

E.g. for the Ising model:

$$\pi = \begin{pmatrix} e^{\beta/2} & e^{-\beta/2} \\ e^{-\beta/2} & e^{\beta/2} \end{pmatrix}$$

(Can be written as "conventional" Feynman)

with

i.e. $P = |0\rangle \langle \alpha, \alpha, \alpha, \alpha| + |1\rangle \langle \beta, \beta, \beta, \beta|,$

$|\alpha\rangle = \sqrt{\pi} |0\rangle; \quad |\beta\rangle = \sqrt{\pi} |1\rangle.$

For this state $|\psi(\beta)\rangle,$

$$\langle \psi(\beta) | \sigma_i^z \sigma_j^z | \psi(\beta) \rangle =$$

$$= \sum_{s_1, \dots, s_N} e^{-\beta H(s_1, \dots, s_N)} \langle s_1, \dots, s_N | \sigma_i^z \sigma_j^z | s_1, \dots, s_N \rangle$$

$\Rightarrow \langle \psi(\beta) | \sigma_i^z \sigma_j^z | \psi(\beta) \rangle$ equals the
 correlation in the classical Gibbs state
 $e^{-\beta H}$!
 (Same for more complex σ^z correlators.)

Such a construction for $|\psi(\beta)\rangle$ can be done
 for any classical Hamiltonian — this can be
 seen e.g. since

$$|\psi(\beta)\rangle = \prod e^{-\beta/2 h_i} |+\rangle^{\otimes N}$$

commute, & any of these
 operators can be written as
 a small local TN.

g) PEPS with critical correlations

2D classical models, e.g. Ising model,
undergo phase transitions at some crit.
temperature β_{crit} .

$\Rightarrow e^{-\beta_{\text{crit}} H}$ has algebraically decaying
correlations!

$$\langle \psi(\beta_{\text{crit}}) | \sigma_i^z \sigma_j^z | \psi(\beta_{\text{crit}}) \rangle \sim \frac{1}{|i-j|^{2\Delta_\sigma}}$$

with some exponent ("scaling dimension") Δ_σ .

\Rightarrow PEPS can exhibit critical correlations.

Exponential clustering theorem: H gapped

\Rightarrow ground state of H has exp.
decaying correlations.

\Rightarrow PEPS can describe states which are not ground states of gapped local Hamiltonians.

a) Partition functions of class. statistical models

H class. Ham., e.g. Ising ($H = -\sum_{\langle ij \rangle} s_i s_j$).

$$\begin{aligned} \text{Partition function } Z &= \text{tr}(e^{-\beta H}) \\ &= \sum_{s_1, \dots, s_n} e^{-\beta H(s_1, \dots, s_n)} \end{aligned}$$

Z is a tensor network:

e.g. trace $Z = \langle \psi(\beta) | \psi(\beta) \rangle$,

or (more efficiently), e.g. for Ising:

$$\text{with } \begin{array}{c} \beta \\ \alpha \text{---} \gamma \\ \gamma \end{array} = \delta_{\alpha=\beta=\gamma=\gamma} ,$$

and
$$\Pi = \begin{pmatrix} e^{+\beta} & e^{-1} \\ e^{-1} & e^{+\beta} \end{pmatrix} .$$

3. Numerical PEPS algorithms

a) Computation of expectation values

Exp. values for MPS:

Transfer operator

$\Rightarrow \langle \psi | O | \psi \rangle = \dots \mathbb{E} \cdot \mathbb{E} \cdot \mathbb{E}_O \cdot \mathbb{E} \dots$

Exp. values for PEPS:

Define transfer operators:

Then,

\Rightarrow 2D expectation values map to contraction of 2D tensor network (vs. 1D TN is RPS = matrix multiplication)

Can this still be done efficiently?

contraction cuts # of indices prop.
 to length of boundary
 \Rightarrow no efficient choice possible —
 for any contraction order length of
 boundary will go up to $O(L)$ for
 $L \times L$ syst.

Contraction of 2D PEPS is "exponentially
hard!"

More precisely: It is NP-hard, in fact,

it is a #P-complete (or rather: Gap P -
 the difference of two #P functions) problem.
 ($\hat{=}$ evaluating path integrals)

\Rightarrow We need to resort to approximate
contracta methods!

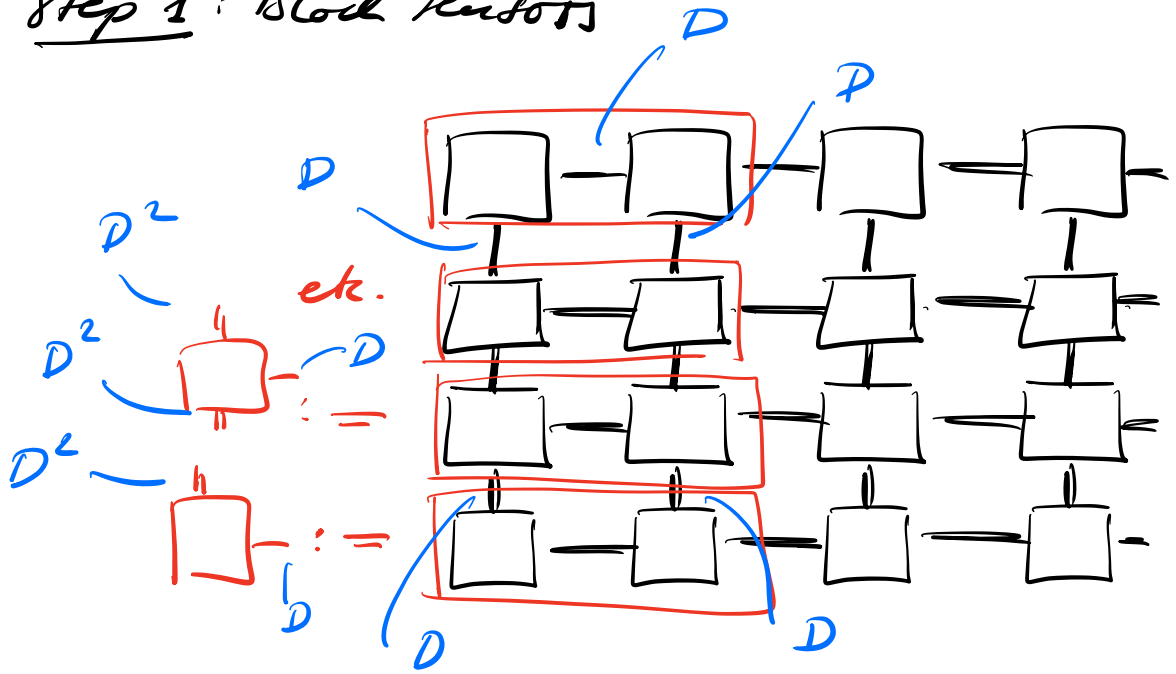

b) Approximate contracta schemes

Two different types of schemes.

i) Column-wise contracta

Case I: Finite (non-Inv.) syst:

Step 1: Block tensors

Step 2 : Truncate new ketons

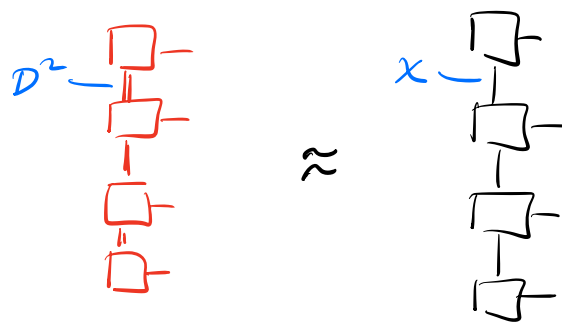

and iterate ... (in the next steps, this

becomes $\begin{matrix} \square & \square & \dots & \rightarrow & \square & \approx & \square \\ | & | & & & | & & | \\ \chi & D & & & \chi D & & \chi \\ \vdots & \vdots & & & \vdots & & \vdots \end{matrix}$)

χ controls accuracy of approximation.

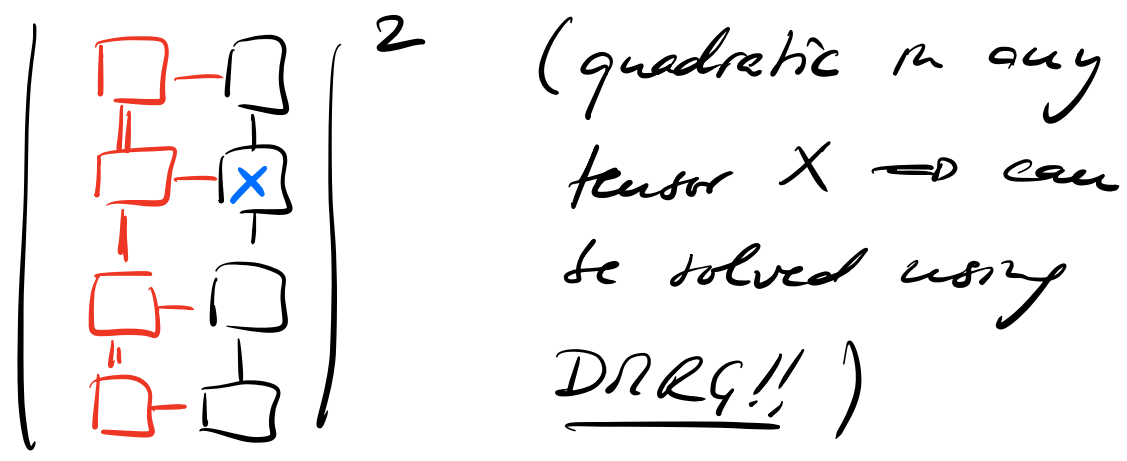

Approximately

can be done in different ways, which

can be derived from 1D algorithms

- truncated by SVD
- maximization of overlap

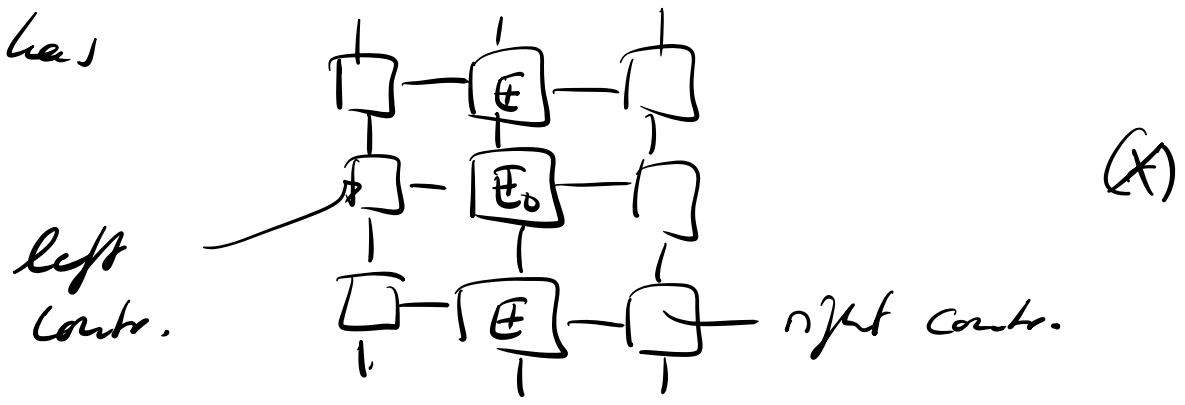

Case II: refactor systems

Works the same way, but use refactor 1D algorithms for contraction (including more sophisticated methods, such as tangent space/UNRPS).

After contracting ϵ from left & right identity,

one has

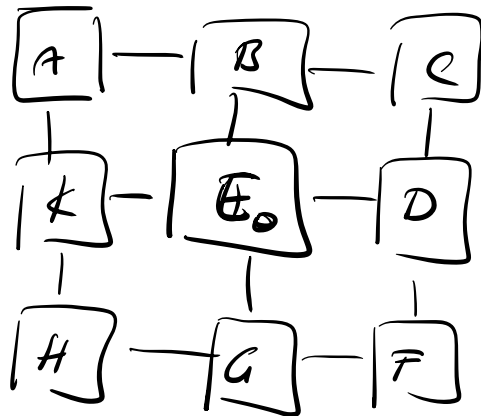

which is a 1D problem \Rightarrow eff. Contractate.

- If the transfer matrix is hermitian, one can also find its leading eigenvalue variationally, i.e. by maximizing (*) w/ same left + right vectors.

ii) Cornes transfer matrix (CTM)

- method for infinite systems
- approximate the "environment" of the site of interest by

- environment tensors are determined by inserting rows/columns of $\begin{bmatrix} | & \cdot & | \\ \hline \cdot & & \cdot \\ | & \cdot & | \end{bmatrix}$, absorbing them in boundary tensors, and truncating.

c) Variational method

Can use this as basis for variational algorithm.

Idea as n 1D's

Finite system: $|\psi\rangle$ linear in each tensor \Rightarrow energy

$$E(x) = \frac{\langle \psi[x] | H | \psi[x] \rangle}{\langle \psi[x] | \psi[x] \rangle}$$

$$= \frac{\vec{x} \cdot \mathbf{M} \vec{x}}{\vec{x} \cdot \mathbf{N} \vec{x}}$$

Can be minimized by generalized eigenvalue problem

\Rightarrow DMRG-type algorithm

Hybrid sys: similar to \mathcal{D} :

Use either nat. time evolution (then add into tensor & cut \mathcal{D}), or gradient search.

4. Analytical properties of PEPS

a) Symmetries

PEPS has symmetry: $|\psi\rangle = U_g^{\otimes n} |\psi\rangle$.

→ Symmetries can be encoded locally?

Does the converse also hold? Is there a fund.

theorem for PEPS?

For generic ("injective") PEPS: Yes! - All such PEPS

encode the sym, as above!

However, in 2D there can be fundamentally different ways to encode symmetries:

E.g., sym. can be encoded by 1D
Matrix Product Operators (MPOs),

$$\begin{array}{c} v_g \\ | \\ \square \\ | \\ v_g \end{array} = \begin{array}{c} \square \\ | \\ v_g \\ | \\ v_g \end{array} \quad \left(\begin{array}{l} \text{"pulling through"} \\ \text{formula} \end{array} \right)$$

} generalise to

$$\begin{array}{c} v_g \\ | \\ \square \\ | \\ w_g \end{array} = \begin{array}{c} \square \\ | \\ w_g \\ | \\ w_g \end{array}$$

Gives rise to a (partial) class. of 2D phases
 phases by studying MPO representations
 of sym. group G .

Note: In the product encoding V_g , the 2-cocycle is not a good class. of phases, since locality:

gives equivalent proj. representation $V_g \otimes V_g$
(e.g. $\frac{1}{2} \otimes \frac{1}{2}$ is not spin).

5) Parent Hamiltonians

Parent Hamiltonians can be defined as in \mathbb{D} :

$$S_k = \left\{ \left(\text{Diagram} \right) \mid X \right\} \subset \mathbb{C}^{d^{4L}},$$

dim $S_k \leq D^{4L}$

$\Rightarrow S_k$ not full space as soon as

$$D^{4L} < d^{L^2} \quad \text{or}$$

$$L > 4 \log D / \log d$$

$\Rightarrow H = \sum (\mathbb{1} - \Pi_{S_k})$ is parent Ham.,

Again, for generic PEPS, H (defined on a big enough patch) has a unique ground state.

But: Not always gapped

(e.g. "long PEPS" at end. point)

\Rightarrow algebraic corr. \Rightarrow cannot be

ground state of gapped Ham.,

(once the "exponential clustering theorem"⁴

states: gap \Rightarrow exp. decay of corr. in g. state).
